hp StorageWorks enterprise virtual array

HP WORLD 2003
Solutions and Technology Conference & Expo

- Design features
 - modularity, scalability and density
 - full end to end 2Gbps fibre channel performance
 - host, infrastructure, controllers and disks
 - high availability with vRAID and component redundancy
 - centralized, lite-touch management
 - storage array based virtualization architecture
 - lower TCO and increase ROI
save time, space and money
- Target deployments
 - enterprise open system data center operations
 - VLDB, OLTP, ERP, CRM
 - HP-UX, OpenVMS, Tru64, Windows NT/ 2000, Red Hat/SUSE Linux, Solaris, IBM AIX, Netware

page 1

The HP StorageWorks enterprise virtual array is executing on the advantages of virtualization at the storage system level enabled by SANworks VersaStor technology by hp.

While virtualization is being addressed by hp at all levels of the SAN, the most powerful application of this technology today is at the storage system level. With the HP StorageWorks enterprise virtual array, organizations are able to take advantage of the many benefits of virtualization with a solution designed specifically for open systems.

hp enterprise virtual array

■ Features

- scaleable modular networked storage
- higher storage capacity utilization
- high capacity in dense packaging footprint
- centralized and simplified management
- auto load balance & self-tuning performance
- hot-swap redundant components, vRAID 0, 1, 5
- 2Gbps fibre channel array controller
- up to 35TB, up to 240 fibre channel 1" HDDs behind single pair of array controllers
- 1GB cache per controller
- centralized management via SAN Appliance

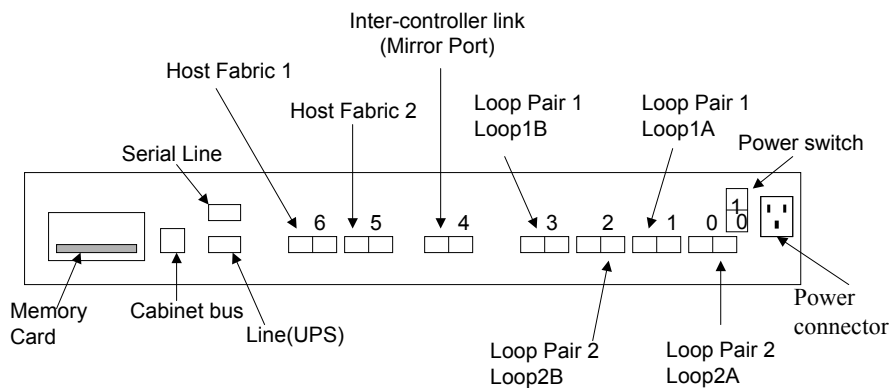

HP StorageWorks Online Storage Portfolio

HP WORLD 2003
Solutions and Technology Conference & Expo

page 3

HSV array controller connectors—rear view

page 4

M5214—drive enclosures— front view

- 3U disk enclosure
- Dual redundant active-active 2Gb/s FC busses
- Fourteen 1-in. FC disks per enclosure

page 5

From the front, with disks installed, it is hard to distinguish a FC drive enclosure from a SCSI drive enclosure.

This view shows the smaller FC drive mating connector on the FC drive enclosure backplane, as opposed to the larger SCSI connector on the SCSI drive enclosure backplane.

Only 1" drives, 14 of them, are supported.

The FC drive enclosure supports dual FC busses to the drives. These are redundant and allow for load balancing between the busses. Both busses are active simultaneously.

FC-AL disk drives

- Dual-ported 2Gb/sec FC-AL
- 36GB, 72GB, and 146GB 10K rpm
- 36GB and 72GB 15K rpm
- Up to 120 drives per FC-AL pair

page 6

SCSI drives only have one port, because of the number of signals/pins required for the interface, with no redundancy or load balancing option of a second port. FC drives have two ports, providing redundancy and load balancing.

The SCSI interface has a limited distance that it can support and as a result a limited number of disks per bus. The FC interface allows, in Compaq's implementation up to 120 drives on redundant pairs of FC busses. The redundant pair of busses also allows load balancing, so that if one buss or port is busy, any drive can be accessed on the other buss or port.

In some cases, SCSI and FC drives share the same mechanics, but they are beginning to diverge. Some SCSI drive vendors are designing new drives with lower cost in mind, trading off performance for cost, as the drives have a wide range of applications including PCs and low-end servers. FC drives, on the other hand, are being designed for high performance and high capacity storage applications.

Seagate is our current FC drive vendor.

Terminology

■ Define the term:

- Virtualization
- VRAID
- Disk Group
- Virtual Disk
- LUN
- Host
- Presentation
- Virtual Disk Leveling
- Distributed Sparing
- Virtually Capacity Free Snapshots
- Snap Clones
- Command View EVA
- SAN Script
- Virtual Controller Software

page 7

what is storage virtualization?

The act of abstracting, hiding, or isolating the internal function of a storage subsystem or service from applications, servers, or general network resources.

page 8

Isn't new.

In 1974, IBM introduced Multiple Virtual Storage (MVS), the primary operating system used on mainframes.

MVS evolved over time and was prepackaged with an extensive set of utilities and renamed OS/390. MVS now refers to the base control program in OS/390.

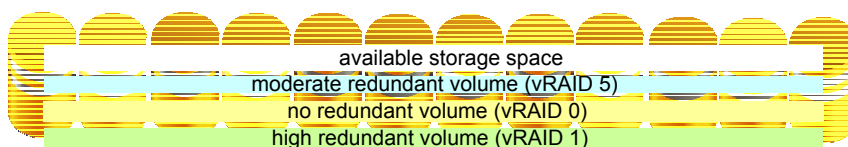

(Source: Techencyclopedia)

hp StorageWorks enterprise virtual array

- traditional storage architecture
- stranded capacity
- storage locked snapshot-space
- under-utilized storage space
- antiquated performance by EVA standards
- - inefficient storage purchase -

maximized storage utilization through virtualization!

page 9

In a traditional storage environment you would purchase as many drives as the server could hold to make sure you did not have to perform an upgrade until the disk is completely full. This leads to your server using only 40-50% of your storage because you were planning on growth that may never happen.

With Virtualization you can carve a LUN (Vdisk) out of the pool of storage starting at 1GB and increasing to 2TB in 1GB increments, this allows you to grow your volumes as needed. No Wasted Space!

enterprise virtual array— VRAID

- Disk load leveling – utilization enhancer
- Distributed sparing – performance & redundancy enhancer
- Space efficient snapshots – utilization enhancer
- Virtual instantaneous snapclones – time savings

page 10

Increased utilization of available capacity

- no need to allocate large files for databases to insure you don't exceed the size of the allocated database. With enterprise you can easily expand the database dynamically interrupting the application

Eliminate stranded capacity

- No longer need to create a volume large enough to handle the anticipated level of activity for the volume and then find you've over-allocated and locked out the disk space

Reduce capacity requirements with “virtually capacity-free” snapshots

- No need to allocate a block of disk space equivalent in size to the disk to get the snapshot.

Manage overall utilization at higher levels

- Utilize more of your disk by reducing the amount of stranded capacity and space needed for 'virtually capacity-free' snapshots

Capacity-on-demand virtual disks

- Easily expand the size of your disk pool by adding physical disk drives without interrupting your applications. Enterprise will automatically evenly distribute the files across all physical disks. When a virtual disk is reaching its capacity, simply enter the additional space needed and virtual disk will automatically expand to the new size.

Virtual Disk redundancy:

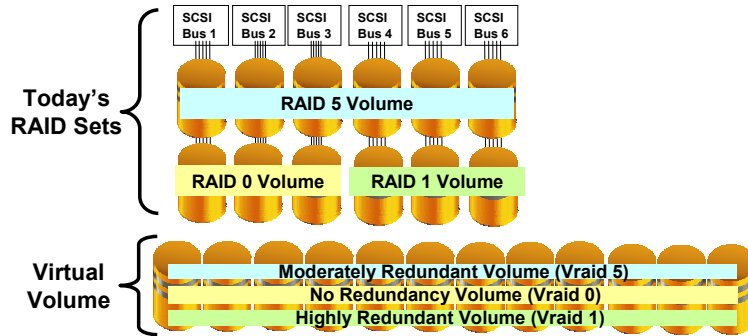

None (VRAID0): Data is striped across all physical disks in the Disk Group.

Moderate (VRAID5): Data is striped with parity across all physical disks in the Disk Group. Always 5 (4+1) physical disks per stripe are used.

High (VRAID1): Data is striped mirrored across all physical disks (even number of them) in the Disk Group. Established pairs of physical disks mirror each other.

VRAID versus RAID

- Eliminate throughput bottlenecks
- Workload is evenly distributed across all spindles in group
- Eliminate load balancing procedures for application and database

page 11

terminology—disk group

- Group of physical disks, from which virtual disks will be created
- Minimum of 8 disks

The screenshot shows the HP StorageWorks Command View EVA interface. The main window displays the 'Initialize an HSV Storage System' wizard. The left pane shows a tree view with 'HSV Storage Network' expanded, showing 'Uninitialized Storage System' and 'Hardware'. The right pane shows the wizard steps: 'STEP 1: Enter a Name' and 'STEP 2: Enter the number of disks'. The 'Finish' button is highlighted.

HP StorageWorks
command view EVA

Appliance: SMAD112FK31K014 10.1.12.12

Root View | Agent Options | Help

Initialize an HSV Storage System

Page 1 | **Initialize** | Cancel

Finish | Advanced options | Cancel

Complete this step and click **Finish** to initialize your HSV storage system in the simplest way possible. If you'd like more control over the initialization of your HSV storage system, complete the step and click **Adv Options** instead.

STEP 1: Enter a Name
Enter a name for your HSV storage system.
[EVA] ?

STEP 2: Enter the number of disks
Enter a number of disks between 8 and 12. (You can add more disks later, if you wish.)
8 ?

page 12

sizing HSV disk groups— considerations disk count formula

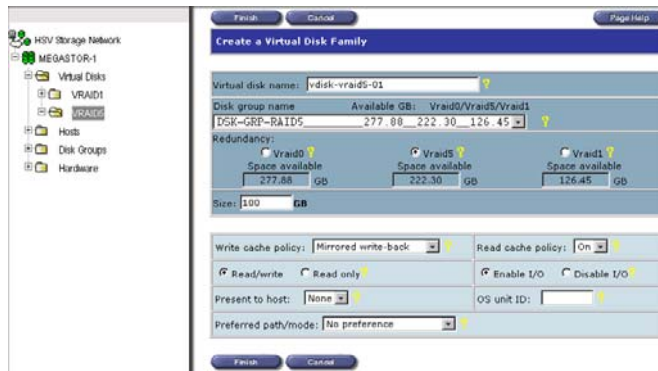

- Hardware versus software capacities
 - Physical 1000 000 000Bytes = 1GB
 - Software 1073 741 824Bytes = 1.07GB Physical (230)
 - ~ 7% Variance → 1GB Physical = 0.93GB Software
- System metadata overhead — 0.2%
 - System metadata
 - MLD—HSV Element Manager metadata
 - Virtual Disk metadata
- Vraid overhead
 - Vraid0 — 0% (1 block for every 1 block usable)
 - Vraid1 — 50% (2 blocks for every 1 block usable)
 - Vraid5 — 20% (1.25 blocks for every 1 block usable)
- Snapshot working space
 - Snap — capacity of original is “allocated” or dependent on rate of change of original data
 - Snapclone — same physical capacity as virtual disk
- Spare capacity
 - 2 X physical capacity of the largest physical disk X protection selected

page 13

terminology—virtual disk

- Logical disk with certain attributes
- Resides in a disk group

The screenshot shows a storage management interface with a left-hand tree view and a main configuration window titled 'Create a Virtual Disk Family'.

Left-hand tree view:

- HSV Storage Network
 - Virtual Disks
 - VRaid1
 - VRaid5**
 - Hosts
 - Disk Groups
 - Hardware

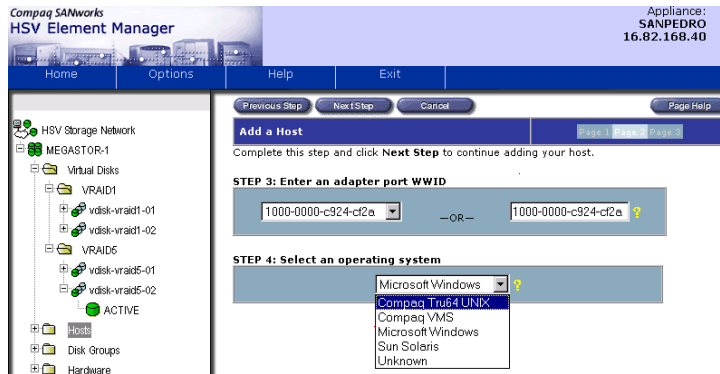

Main configuration window 'Create a Virtual Disk Family':

- Buttons: Finish, Cancel, Page Help
- Virtual disk name: vdisk-vraid5-01
- Disk group name: Available GB: Vraid0/Vraid5/Vraid1
- Disk group: DSK-GRP-RAID5 (277.88 222.30 126.45)
- Redundancy:
 - ☒ Vraid0 (Space available: 277.88 GB)
 - ☒ Vraid5 (Space available: 222.30 GB)
 - ☐ Vraid1 (Space available: 126.45 GB)
- Size: 100 GB
- Write cache policy: Mirrored write-back
- Read cache policy: On
- ☒ Read/write ☐ Read only
- ☒ Enable I/O ☐ Disable I/O
- Present to host: None
- OS unit ID:
- Preferred path/mode: No preference
- Buttons: Finish, Cancel

page 14

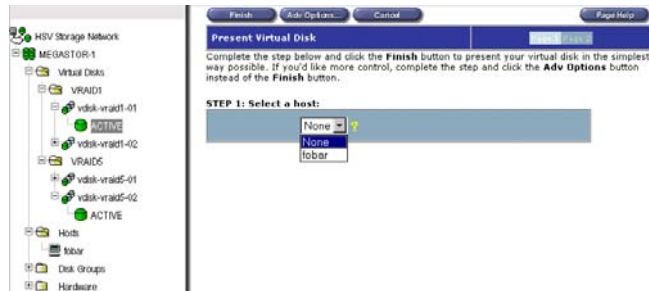

terminology—host

- Collection of HBAs, that reside in the same (virtual) server

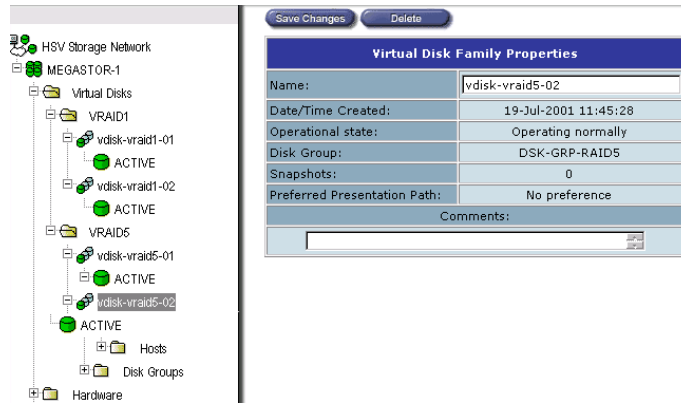

terminology—presentation

- A persistent instruction to make a specified virtual disk available to all adapters on the specified host as the specified SCSI LUN

terminology—LUN

- Virtual disk presented to one or more hosts

The screenshot displays the HP Storage Management console interface. On the left, a tree view shows the hierarchy: HSV Storage Network > MEGASTOR-1 > Virtual Disks > VRAID1 > vdisk-vraid1-01 > vdisk-vraid1-02 (ACTIVE). Below this, VRAID5 is shown with vdisk-vraid5-01 (ACTIVE) and vdisk-vraid5-02 (ACTIVE). The right pane shows the 'Virtual Disk Family Properties' for 'vdisk-vraid5-02'.

Virtual Disk Family Properties	
Name:	vdisk-vraid5-02
Date/Time Created:	19-Jul-2001 11:45:28
Operational state:	Operating normally
Disk Group:	DSK-GRP-RAID5
Snapshots:	0
Preferred Presentation Path:	No preference
Comments:	

page 17

terminology—virtual disk leveling

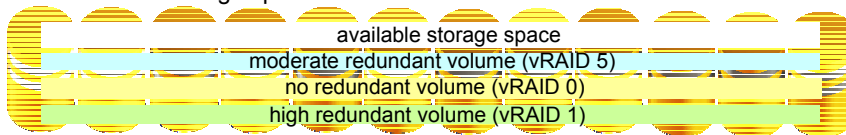

- dynamic pool capacity changes
- pool capacity can be expanded by spindle(s)
- virtual disk blocks are automatically relocated to level spindle use
 - disk spindles becoming a throughput bottleneck
 - no additional storage space available

||

- disks running at optimum throughput (dynamic load balancing)
- additional storage space available

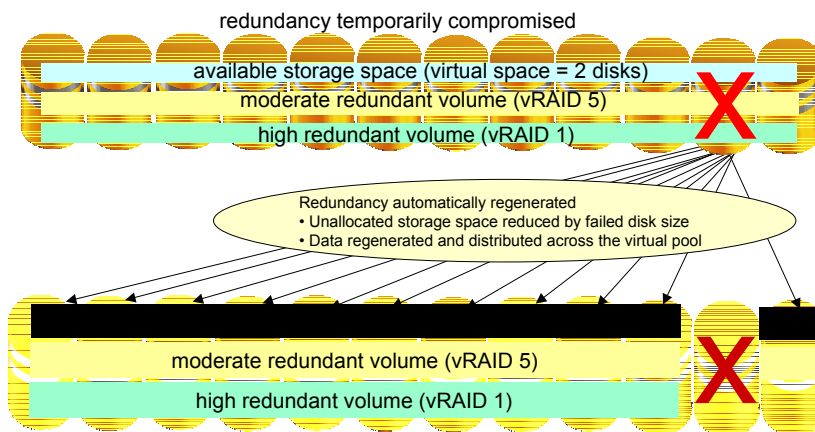

page 18

With virtualization you can now manage by attribute, think of only blocks not disks... In the upper diagram let's assume that there are 100 72GB drives in the pool. You also have a 100GB database on a server attached to the EVA, therefore there would be 1GB of blocks on each drive. Now add the 3 drives for the diagram at the bottom, this will now span 103 drives but the database will still only be 100GB, this allows performance to increase because the data is automatically distributed to the other 3 drives.

terminology—distributed sparing

- virtual disk blocks automatically regenerated to restore redundancy

page 19

Think about all the servers that you have.... Now think about each array having a separate spare drive in case a drive fails in the middle of the night... That is probably a large number of drives...

In the EVA we use a process called distributed sparing, this process allows us to add the spare drives into the disk pool for performance and we take the capacity of those drives out of the pool to allow for a failed drives VD data to be moved into that space.

With the EVA we change the process of sparing and give you extra performance as well.....

GO TO NEXT SLIDE for better example

terminology—distributed sparing sizing

- Chunks allocated, but not dedicated as spares drives to survive 1 or 2 disk drive failures

■ Example:

- Disk Group: 8 * 36G, Protection level: Single
 - Total Disk Group size: $8 * 36 = 288$ GB
 - Maximum size for Virtual Disks $(8 - (1 * 2)) * 36 = 216$ GB
- Disk Group: 120 * 36G, Protection level: Double
 - Total Disk Group size: $120 * 36 = 4.32$ TB
 - Maximum size for Virtual Disks $(120 - (2 * 2)) * 36 = 4.18$ TB

BECAUSE
YOU ASKED

- Note: This does not account for difference between physical and software GB, more later

page 20

terminology—snapshots (point-in-time)

- vsnaps - virtually capacity free snapshots
 - pointer-based copies - eliminates need to purchase additional physical capacity just to store replication copies
 - enables new backup methodologies and expedited recovery
 - data pointers copied to unused space
- Snapshots can also be set to fully allocated

page 21

The enterprise virtual array controller provides three types of data replication tools:

Traditional snapshot

Virtually Capacity-Free Snapshot

Virtually Instantaneous Snapclone

These data migration and replication tools have been refined in the enterprise virtual array to provide tremendous flexibility and data protection.

What are Virtual snapshots?

Virtual disk snapshots, or Vsnaps, are disk-based copies that reduce backup windows to seconds. This is achieved by replicating pointers to data — instead of the data itself.

Benefits and value of Vsnaps:

Snapshots of virtual disks are virtually capacity-free

Ad hoc Vsnaps can be taken in seconds

Vsnaps require minimal physical capacity; only modified blocks take space

Vsnaps can be mounted in seconds for disk-based recovery

Vsnaps can be mounted and copied to tape anytime for archive

There are two Snapshot options:

Traditional Snapshot is the standard way of doing snapshots where an exact amount of space is reserved, equal to the original Virtual Disk or LUN.

Virtually Capacity Free Snapshot, which uses space for the snapshot only as required as the original copy changes. This is a feature most competitors do not have.

terminology—snapclone (point-in-time)

- snapclone - virtually instantaneous replication
 - combines the best of snapshot and clone (physical copy)
 - provides virtually instantaneous Snapclone data replication
 - similar to snapshot
 - data cloned to second set of disks in background
 - data available after snap

page 22

What are Snapclones?

A Snapclone integrates the best features of Vsnapshots and clones with automation to provide the ultimate data mining solution. Independent physical clone copies of data can be accessed instantaneously — rather than waiting for the complete physical movement of the data.

Benefits and value of Snapclone:

Enables application and live testing of data without disrupting business operations

Can be mounted and copied to tape for archive

Enables data to be relocated from main data center in case of site disaster

Virtually Instantaneous Snapclone is a new implementation of clone or copy, which can save customers time and money.

Virtually Instantaneous Snapclone is an improved type of data cloning similar to a traditional clone because duplicate space is reserved. A complete copy of the original virtual disk is made as quickly as data transfer rates permit, resulting in two identical independent copies of the data in the shortest time possible.

There is an important difference between Virtually Instantaneous Snapclone and the traditional clone. With traditional controllers, the clone copy is not available until the copy is complete. With Virtually Instantaneous Snapclone, the snapclone data can be accessed virtually immediately.

terminology—Command View EVA

- Application to manage Enterprise Virtual Array
- Runs on OpenView Storage Management Appliance

page 23

Command View EVA

- Provides the ability to configure the following on Enterprise:
 - Can Initialize Enterprise
 - Enables, via purchased “keys,” Base HSV controller software, Snapshot, DRM (future)
 - Manages
 - Virtual Disks
 - Manages Physical Store (disk drives)
 - Manages HSV Controllers
 - Manages Enterprise Drive Enclosures

page 24

This slide outlines the basic Configuration features of the HSV Element Manager.

terminology—Storage System Scripting Utility (SSSU) aka SANscript

- Tool to issue commands through a shell UI and execute scripts
- Scripts to create/modify a configuration
- Interactive mode as a command prompt
- Configuration commands to add, set, and delete
- Capture of a configuration into a script file
- Show command to display configuration
- Establishes a session with HSV agent on SAN Management Appliance

A screenshot of a command-line window titled "E:\Management\SANscript.exe". The window shows the following text:

```
SANscript: SSSU version 2.0 Build 88 on Jun 17 2003 at 18:26:18  
[C:\Program Files\SSSU] Version 1.5 8236, Build date: Jun 19 2003  
NoCellSelected> select manager fraggle user=administrator pass=admin  
NoCellSelected> show cell  
Cells available on this Manager:  
NoCellSelected> select cell "HSV Storage System"  
HSV Storage System> add storage Accounting size=12  
HSV Storage System> show storage  
Storage available on this Cell:  
- Virtual Disk Accounting\VC1008  
HSV Storage System>
```

page 25

virtualization controller software v3.0

- non-disruptive download firmware updates
 - controllers, EMU and disk drives
 - controller code
 - distributed with controller hardware from the factory
 - updates distributed on CD-ROMs and updated from the SAN Appliance
 - enabled (base, snapshot and, later, DRM) by software license keys which are managed by SAN Appliance / HSV element manager
 - support for:
 - dual redundant controllers
 - mirrored cache, 1GB per controller, running across a dedicated 2Gb/s FC port
 - support for multi-bus failover (native or with Secure Path)
 - support for up to 512 hosts
 - support for up to 512 LUNs / virtual disks (a max of 256 LUNs per HBA*)
 - support for up to 1024 HBAs
 - support for SMART environmental monitoring unit (EMU)
 - Continuous Access EVA Disaster Tolerant configurations
- *Some HBAs won't support a max of 256 LUNs. The HBA used with IBM AIX will only support 16 LUNs. The HBAs used with HP-UX will support 128 LUNs.

page 26

- **Another important feature is non-disruptive download of controller software, EMU firmware and drive firmware.**
- **The controller code is no longer distributed on PCMCIA cards, like it is on the HSG80. It is stored in flash memory on the controllers when they leave the factory. New code can be distributed on CD-ROMs (later electronically over the web, but not at first release). The code is enabled, including Base and Snapshot (and later DRM) with Software License keys which are managed by the HSV Element Manager running on the SAN Appliance.**

CONTINUOUS ACCESS

page 27

Continuous Access concepts

- What is Continuous Access EVA ?
 - CA copies data online and in real time via synchronous replication to remote locations through a local or extended SAN

page 28

Continuous Access for EVA Terminology

- Source
 - EVA with Data Replication functionality, which acts as the master for a Data Replication (DR) Group
- Destination
 - EVA with Data Replication functionality, which acts as the slave for a given DR Group
- Copy Set (CS)
 - Relation between a virtual disk on a source EVA and a virtual disk on a destination EVA. Data is copied from the source to the destination. A copy set is uni-directional
- Data Replication (DR) Group
 - A collection of 1 or more copy sets, logically grouped together, usually for data consistency reasons

page 29

XP Terminology:

Remote Copy Set equals to CA-pair (Continues Access Pair)

Association Set equals to Consistency Group

Continuous Access for EVA Data Replication (DR) Groups and Managed Sets

- DR Group characteristics
 - A DR Group is a collection of 1 or more copy sets which share the following common attributes
 - exist in the same EVA
 - they share a log
 - if one copy set fails, host access is removed from all other copy sets as well (for failsafe_mode = enabled)
 - I/O ordering is kept across all copy sets
 - all copy sets failover together
 - In other words: DR Groups are used by a host to keep multiple copy sets consistent with one another

page 30

Continuous Access for EVA Terminology

page 31

Continuous Access for EVA Terminology

- Log space
 - Space taken from a disk group that will be used when a DR Group starts logging
 - Log space is taken from the disk group with the most available free space, by default, when more than one disk group exists
 - Log space is “per DR Group” and can grow to either 2TB, 2xDR Group membership size, or all available disk group free space (minus protection level), whichever comes first
- Command View EVA
 - Web-based application for managing/configuring EVAs
- CA-UI
 - Abbreviation for Continuous Access User Interface. Web-based application. Server part resides on the SAN Appliance
- Managed Set
 - Collection of DR Groups that can be failed over all at once by CA-UI. May span multiple EVA CA configurations

page 32

Managed Sets are only available via DRM-UI (aka Doctor MUI)

We always use logging and cannot be switches off.

Continuous Access for EVA Data Replication (DR) Groups and Managed Sets

■ Managed Sets

- A Managed Set is a collection of DR Groups which share common attributes, say:
 - are used by the same line of business
 - all DR Groups within an EVA
- A Managed Set may span multiple EVA CA setups
- Only available in CA-UI, not in Command View EVA
- Managed sets are used by an end-user to group DR groups into a single management entity

page 33

Continuous Access for EVA Terminology

page 34

Continuous Access for EVA Feature Set

- 64 Copy Sets
- Up to 8 Copy Sets per DR Group
- 256 Vdisks (this includes snapshots & snapclones, and 7 snap or snapclone per Vdisk on either source or destination, but not both)
- Synchronous Replication
- Bi-directional Replication
 - On DR Group level
- No restriction on virtual disk characteristics
 - Size: 1GB \leftrightarrow 2 TB
 - Vraid levels : 0*, 1 and 5

page 35

So no asynchronous in final version.

Try to avoid Vraid0 as long as possible.

Continuous Access for EVA Feature Set

- **Dynamic expansion of virtual disks** (for OS's that support this feature)

- **ISLs can use:**
 - DWDM
 - FC-IP
 - Multi Mode Fiber/Single Mode Fiber

- Up to 16 Disk Groups per storage system

- Members of a DR Group can reside in different disk groups

page 36

Continuous Access for EVA Feature set

- Management:**
 - Continuous Access User Interface (CA-UI)
 - Command View EVA
 - Scripting (SSSU)

page 37

Continuous Access for EVA

Synchronous and Asynchronous Copy Modes

■ **Synchronous Mode**

- Remote site data is constantly kept consistent with local site data
- I/O completion status is not returned to the host until both the local and remote writes (to cache) are complete
- Provides real-time mirroring of data
- In-order delivery is guaranteed (using Group Sequence Numbers (GSNs))
- Appropriate when exact data consistency is crucial to the application

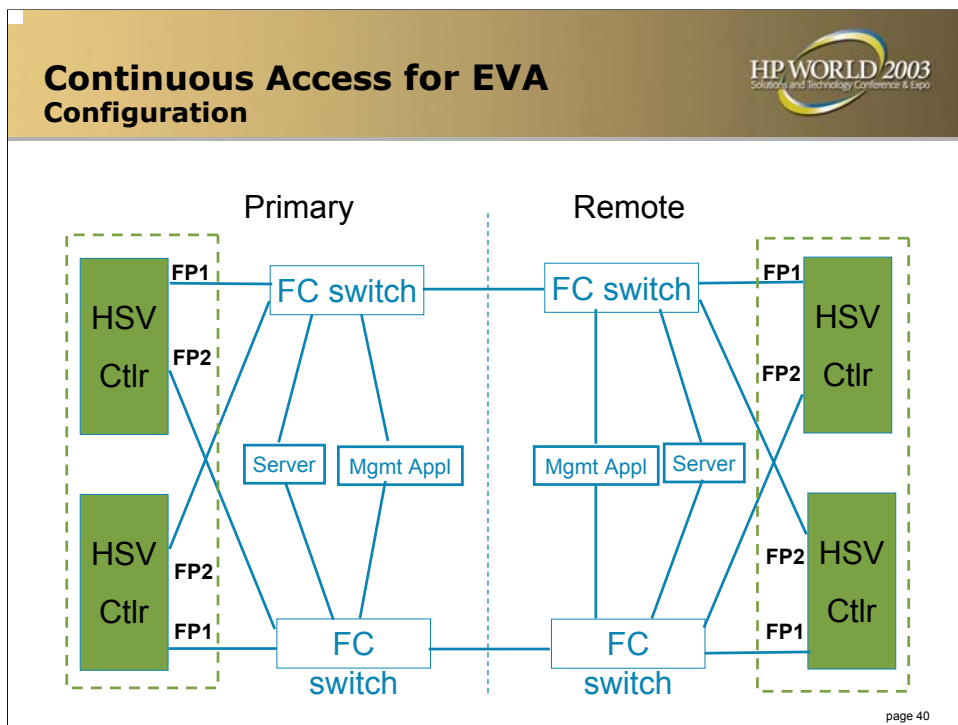

page 38

Continuous Access for EVA Synchronous and Asynchronous Copy Modes

■ Synchronous Mode

- Synchronous mode can affect overall performance by increasing response time on writes
- The higher the latency of the link, the more impact on performance
- Synchronous mode is what VCS V3.0 uses

2 SANAppliances, being 1 per site. Advised is to have the SWMA on the primary site shutdown and manage everything from the SWMA on the remote site. On the SWMA, 2 components are important: HSV Element Manager and DRM-UI. The SWMA must be able to 'see' both the Source and Destination Storage System.

HSV controllers are cross-wired, thus allowing fabric failover on the same controller and load balancing over both ISL's

DRM traffic is preferred to FP1. This is true for V3 and may change in V4 (so that it will use FP2 as well)

FP means Fabric Port

DP means Device Port

MP means Mirror Port

DRM-UI does NOT have access to the MLD. hence the

multi operating system support

- Windows NT/2000
 - secure path v4.0A
- HP-UX 11.0 and 11.i
 - MC Service Guard
 - 11.13 and 11.14
 - secure path v3.0A
- Tru64 UNIX 5.1, 5.1a and 5.1b
- OpenVMS
 - 7.2-2 with Fibre_SCSI-V0200
 - 7.3
- Netware 5.1, 6.0
 - secure path v3.0C
- SUN Solaris 2.6, v7 and v8
 - VERITAS Clustering v1.3
 - SUN Cluster v2.2
 - PCI, cPCI & S-Bus HBAs
 - secure path v3.0A/3.0B
- IBM AIX
 - HACMP certification
 - 4.3.3 and 5.1
 - secure path v2.0C
- Linux (x86)
 - Red Hat 7.2
 - Advanced Server 2.1
 - SLES 7
 - secure path v3.0

page 41

Solutions and Technology Conference & Expo

Interex, Encompass and HP bring you a powerful new HP World.

Reference Information

page 43

Continuous Access for EVA Configuration Rules

- Cabling method of EVA host ports to allow fabric failover per controller
- SAN Appliance
 - Minimum of 2, so 1 per site
 - Both HBAs of each OV Storage Mgmt Appliance must be connected to a different fabric
 - Must be able to “see” both source and destination EVA
 - **Only one** OV Storage Mgmt Appliance may be actively monitoring the EVAs
 - Hops between the local OV Storage Mgmt Appliance and the local EVA are **not** allowed
- Destination virtual disk can not already exist
- Maximum of 7 hops between source and destination EVA
- Minimum of 4 FC Switches in 2 Fabrics
- 2 ISLs, 1 per Fabric

page 44

Continuous Access for EVA Comparison with DRM on HSG80

EVA

- Nr of CS's: 64
- Nr of DR Groups: 64
- Copy methods:
 - Synchronous
- Nr of CS's per DR Group: 8
- Not applicable due to architectural difference
- Always uses write history log
 - Always ORDER_ALL
- Max CS size: 2 TB

HSG80

- Nr of RCS's: 12
- Nr of association sets: 12
- Copy methods:
 - Synchronous
 - Asynchronous
- Nr of RCS's per association set: 12
- No controller based partitions of RCS's
- Write history log *optional*
 - NOORDER_ALL is default
- Max RCS size: 1.1 TB

page 45

page 46

XP: Fence level=Data equals to Failsafe Mode=Enabled

Still to be determined whether DRM is a capacity or a feature license.

Continuous Access for EVA

Comparison with Continuous Access on XP

EVA

- Nr of remote copy sets: 64
- Nr of DR groups: 64
- Copy methods:
 - Synchronous
- Nr of remote copy sets per DR group: 8
- Write history log limited to 2 TB / available disk pool space
- Max RCS size: 2 TB

XP

- Nr of CA pairs: 4096 (or 8192)
- Nr of consistency groups: 128
- Copy methods:
 - Synchronous
 - Asynchronous
- Nr of CA pairs per consistency group: ??
- Write history log limited by cache size
- Max CA pair size: 1.3 TB

page 47

XP: Consistency Groups only used for async (which is used for > 10km)

XP: Site File equals to Write History Log. Max is limited to a certain (settable) amount of shared memory. Typical 30%.
